29 October

Hi Timothy,

I'd add a regression case where checkout A gets a clean result after checkout B has started, then check that B's recovery email stays blocked until B is classified. That tests the exact risk your brief describes: a delayed result for one checkout authorizing a send for another on the same profile.

I'd also run the case with duplicate and repeated events before approving a flow restart, while checking that any proposed suppression leaves legitimate purchasers, active quotes, and institutional prospects eligible.

Allen
